The Boltzmann theory approach to transport:

A very false approach for correlated matter, unfortunately very
Strongly influential and pervasive.

Need for alternate view point.
Vulcan death grip – Derived from a Star Trek classic episode where a non-existent "Vulcan death grip" was used to fool Romulans that Spock had killed Kirk.
First serious effort to understand Hall constant in correlated matter:

Introduced object
\[ R_H^* = \lim_{B \to 0} \lim_{\omega \to \infty} \rho_{xy}(\omega) / B \]

• Easier to calculate than transport Hall constant
• Captures Mott Hubbard physics to large extent

Motivation: Drude theory has
\[ \sigma_{xy}(\omega) = \sigma_{xy}(0) / (1 + i\omega\tau)^2 \]
\[ \sigma_{xx}(\omega) = \sigma_{xx}(0) / (1 + i\omega\tau) \]

Hence relaxation time cancels out in the Hall resistivity
\[ \rho_{xy}(\omega) = \frac{\sigma_{xy}}{(\sigma_{xx})^2} \]
\[ \tau^{xx} = \frac{q_e^2}{\hbar} \sum \eta_x^2 \ t(\vec{\eta}) \ c_{\vec{r}+\vec{\eta},\sigma}^\dagger c_{\vec{r},\sigma} \]

\[ \tau^{xy} = \frac{q_e^2}{\hbar} \sum \vec{k},\sigma \ \frac{d^2 \varepsilon_{\vec{k}}}{dk_\alpha dk_\beta} \ c_{\vec{k},\sigma}^\dagger c_{\vec{k},\sigma} \]

\[ \sigma^{\alpha,\beta}(\omega_c) = \frac{i}{\hbar N_s \nu \omega_c} \left[ \langle \tau^{\alpha,\beta} \rangle - \hbar \sum_{n,m} \frac{p_n - p_m}{\epsilon_n - \epsilon_m + \hbar \omega_c} \langle n|\hat{J}_\alpha|m\rangle \langle m|\hat{J}_\beta|n\rangle \right] \]
\[ D_c = \frac{1}{N_s v} \left[ \langle \tau^{xx} \rangle - \hbar \sum_{n,m} \frac{p_n - p_m}{\epsilon_m - \epsilon_n} |\langle n| \hat{j}_x |m\rangle|^2 \right]. \]

\[ \omega_{p,s}^2 = \frac{4\pi q_e^2 \rho_s(T)}{m} = \frac{4\pi D_c(T)}{\hbar} \]

\[ \text{Superfluid stiffness} \]

\[ \text{Re } \sigma(\omega) = \pi \delta(\hbar \omega) D_c + \frac{\pi}{N_s v} \left( \frac{1 - e^{-\beta \hbar \omega}}{\omega} \right) \sum_{n,m} p_n |\langle n| \hat{j}_x |m\rangle|^2 \delta(\epsilon_m - \epsilon_n - \hbar \omega) \]

\[ \text{Plasma sum rule} \]

\[ \omega_p^2 = \frac{4\pi}{\hbar N_s v} \langle \tau^{xx} \rangle \rightarrow \frac{4\pi \rho q_e^2}{m} \]

\[ \int_0^\infty \text{Re } \sigma(\omega) d\omega = \frac{\pi}{2\hbar N_s v} \langle \tau^{xx} \rangle \rightarrow \frac{\omega_p^2}{8} \]
\[ R_H^* = \frac{-iN_s v}{B \hbar} \frac{\langle [J^x, J^y] \rangle}{\langle \tau xx \rangle^2} \]

• Very useful formula since
  • Captures Lower Hubbard Band physics. This is achieved by using the Gutzwiller projected fermi operators in defining J’s
  • Exact in the limit of simple dynamics (e.g. few frequencies involved), as in the Boltzmann eqn approach.
  • Can compute in various ways for all temperatures (exact diagonalization, high T expansion etc.....)
  • We have successfully removed the dissipational aspect of Hall constant from this object, and retained the correlations aspect.
  • Very good description of t-J model, not too useful for Hubbard model.
  • This asymptotic formula usually requires \( \omega \) to be larger than J
Comparison with Hidei Takagi and Bertram Batlogg data for LSCO showing change of sign of Hall constant at delta=.33 for square lattice
As a function of $T$, Hall constant is LINEAR for triangular lattice!!

We suggest that transport Hall = high frequency Hall constant!!

• Origin of $T$ linear behaviour in triangular lattice has to do with frustration. Loop representation of Hall constant gives a unique contribution for triangular lattice with sign of hopping playing a non trivial role.
Anomalous high-temperature Hall effect on the triangular lattice in Na$_{x}$CoO$_2$

Yayu Wang$^1$, Nyrissa S. Rogado$^2$, R. J. Cava$^{2,3}$, and N. P. Ong$^{1,3}$

The Hall coefficient $R_H$ of Na$_x$CoO$_2$ ($x = 0.68$) behaves anomalously at high temperatures ($T$). From 200 to 500 K, $R_H$ increases linearly with $T$ to 8 times the expected Drude value, with no sign of saturation. Together with the thermopower $Q$, the behavior of $R_H$ provides firm evidence for strong correlation. We discuss the effect of hopping on a triangular lattice and compare $R_H$ with a recent prediction by Kumar and Shastry.

Hall constant as a function of $T$ for $x = .68$ (CW metal). $T$ linear over large range 200$^0$ to 436$^0$ (predicted by theory of triangular lattice transport KS)

STRONG CORRELATIONS & Narrow Bands

T Linear resistivity
Phenomenological interpretations of the ac Hall effect in the normal state of YBa$_2$Cu$_3$O$_7$

Anatolev T. Zheleznnyak*, Victor M. Yakovenko†, and H. D. Drew‡

Department of Physics and Center for Superconductivity Research, University of Maryland, College Park, Maryland 20742
Thermoelectric phenomena
\[ \Theta^{xx} = - \lim_{k_x \to 0} \frac{d}{dk_x} [\hat{j}_x^Q(k_x), \hat{K}(-k_x)] \]

Here we commute the Heat current with the energy density to get the thermal operator

\[ Re \kappa(\omega) = \frac{\pi}{\hbar T} \delta(\omega) \bar{D}_Q + Re \kappa_{reg}(\omega) \]

\[ Re \kappa_{reg}(\omega) = \frac{\pi}{TLC} \left( \frac{1 - e^{-\beta \omega}}{\omega} \right) \sum_{\epsilon_n \neq \epsilon_m} p_n |\langle n | \hat{j}_x^Q | m \rangle|^2 \delta(\epsilon_m - \epsilon_n - \hbar \omega), \quad (1) \]

\[ \bar{D}_Q = \frac{1}{L} \left[ \langle \Theta^{xx} \rangle - \hbar \sum_{\epsilon_n \neq \epsilon_m} \frac{p_n - p_m}{\epsilon_m - \epsilon_n} |\langle n | \hat{j}_x^Q | m \rangle|^2 \right]. \quad (2) \]

The sum rule for the real part of the thermal conductivity (an even function of \( \omega \)) follows

\[ \int_0^{\infty} Re \kappa(\omega) d\omega = \frac{\pi}{2\hbar TL} \langle \Theta^{xx} \rangle. \quad (1) \]

Comment: New sum rule.

Not known before in literature.
\[ \kappa(\omega_c) = \frac{i}{T\hbar\omega_c} D_Q + \frac{1}{TL} \int_0^\infty dt e^{i\omega_c t} \int_0^\beta d\tau \langle \hat{J}_x(0) \rangle. \]

Where
\[ D_Q = \frac{1}{L} \left[ \langle \Theta^{xx} \rangle - \hbar \sum_{n,m} \frac{p_n - p_m}{\epsilon_m - \epsilon_n} \langle n|\hat{J}_x|m\rangle^2 \right]. \]

In normal dissipative systems, the correction to Kubo’s formula is zero, but it is a useful way of rewriting zero, it helps us to find the frequency integral of second term, hitherto unknown!!

So, what does \( \Theta \) look like and what is its value? Answer is model dependent, and in brief, \( \Theta \) is the specific heat times a velocity
\[ \frac{\Theta^{xx}}{\hbar T} = \frac{1}{d} C_\mu v_{eff}^2 \]
Thermo-power follows similar logic:

\[
\langle \hat{J}_x \rangle = \sigma(\omega) E_x + \gamma(\omega)(-\nabla T)
\]

then the thermopower is

\[
S(\omega) = \frac{\gamma(\omega)}{\sigma(\omega)}.
\]

\[
\Phi^{xx} = -\lim_{k \to 0} \frac{d}{dk_x} [\hat{J}_x(k_x), K(-k_x)].
\]

This is the thermo electric operator

\[
\gamma(\omega_c) = \frac{i}{\hbar \omega_c T \mathcal{L}} \left[ \langle \Phi^{xx} \rangle - \hbar \sum_{n,m} \frac{p_n - p_m}{\epsilon_n - \epsilon_m + \hbar \omega_c} \langle n|\hat{J}_x|m\rangle \langle n|\hat{J}^Q_x|m\rangle \right].
\]

\[
D_\gamma = \frac{1}{\mathcal{L}} \left[ \langle \Phi^{xx} \rangle - \hbar \sum_{n,m} \frac{p_n - p_m}{\epsilon_m - \epsilon_n} \langle n|\hat{J}_x|m\rangle \langle n|\hat{J}^Q_x|m\rangle \right].
\]

\[
\gamma(\omega_c) = \frac{i}{\hbar \omega_c T} D_\gamma + \frac{1}{T \mathcal{L}} \int_0^\infty dt e^{i \omega_c t} \int_0^\beta d\tau \langle \hat{J}_x(-t - i \tau)\hat{J}^Q_x(0) \rangle,
\]
High frequency limits that are feasible and sensible similar to $R^*$

\[
L^* = \frac{\langle \Theta^{xx} \rangle}{T^2 \langle \tau^{xx} \rangle} \quad (1)
\]

\[
Z^*T = \frac{\langle \Phi^{xx} \rangle^2}{\langle \Theta^{xx} \rangle \langle \tau^{xx} \rangle} \quad (2)
\]

\[
S^* = \frac{\langle \Phi^{xx} \rangle}{T \langle \tau^{xx} \rangle} \quad (3)
\]

Hence for any model system, armed with these three operators, we can compute the Lorentz ratio, the thermopower and the thermoelectric figure of merit!
So we naturally ask
• what do these operators look like
• how can we compute them
• how good an approximation is this?

In the preprint: several models worked out in detail
• Lattice dynamics with non linear disordered lattice
• Hubbard model
• Inhomogenous electron gas
• Disordered electron systems
• Infinite U Hubbard bands

• Lots of detailed formulas: we will see a small sample for Hubbard model and see some tests...
Anharmonic Lattice example

\[ H = \sum_j H_j \]

\[ H_j = \left[ \frac{p_j^2}{2m_j} + U_j \right]; \quad U_j = \frac{1}{2} \sum_{i \neq j} V_{j,i} \]  \hspace{1cm} (1)

\[ J^E_x(\vec{k}) = \frac{1}{4} \sum_{i,j} \frac{(X_i - X_j)}{m_i} e^{ik \cdot X_i} \{p_{x,i}, F^x_{i,j}\} \]

\[ \Theta^{xx} = (\hbar \omega_0^2 a_0^2) \left[ \frac{1}{m} \sum_i p_i p_{i+1} + \frac{k_s}{4} \sum_i (u_{i-1} - u_{i+1})^2 \right] \]

\[ \langle \Theta^{xx} \rangle = \mathcal{L} (\hbar^2 \omega_0^3 a_0^2) \int_0^{\pi} \frac{dk}{\pi} \left[ \left( \frac{1}{2} + \frac{1}{e^{\beta \omega_k} - 1} \right) \left\{ \frac{\omega_k}{\omega_0} \cos(k) + \frac{\omega_0}{\omega_k} \sin^2(k) \right\} \right] \]
Thermo power operator for Hubbard model

\[
\Phi_{xx} = -\frac{q_e}{2} \sum_{\vec{\eta}, \vec{\eta}', \vec{r}} (\eta_x + \eta'_x)^2 t(\vec{\eta}) t(\vec{\eta}') c_{\vec{r}+\vec{\eta}+\vec{\eta}', \sigma}^\dagger c_{\vec{r}, \sigma} - q_e \mu \sum_{\vec{\eta}} \eta_x^2 t(\vec{\eta}) c_{\vec{r}+\vec{\eta}, \sigma}^\dagger c_{\vec{r}, \sigma} + q_e U \frac{1}{4} \sum_{\vec{r}, \vec{\eta}} t(\vec{\eta}) (\eta_x)^2 (n_{\vec{r}, \sigma} + n_{\vec{r}+\vec{\eta}, \sigma}) (c_{\vec{r}+\vec{\eta}, \sigma}^\dagger c_{\vec{r}, \sigma} + c_{\vec{r}, \sigma}^\dagger c_{\vec{r}+\vec{\eta}, \sigma}).
\]  

(1)

This object can be expressed completely in Fourier space as

\[
\Phi_{xx} = q_e \sum_{\vec{p}} \frac{\partial}{\partial p_x} \left\{ v^x_p (\varepsilon_\vec{p} - \mu) \right\} c_{\vec{p}, \sigma}^\dagger c_{\vec{p}, \sigma}
\]  

(2)

\[
+ q_e U \frac{1}{2L} \sum_{\vec{l}, \vec{p}, \vec{q}, \sigma, \sigma'} \frac{\partial^2}{\partial l_x^2} \left\{ \varepsilon_{\vec{l}} + \varepsilon_{\vec{l}+\vec{q}} \right\} c_{\vec{l}+\vec{q}, \sigma}^\dagger c_{\vec{l}, \sigma} c_{\vec{p}-\vec{q}, \sigma'}^\dagger c_{\vec{p}, \sigma'}.
\]  

(3)

\[
\tau_{xx} = \frac{q_e^2}{\hbar} \sum_{\vec{\eta}} \eta_x^2 t(\vec{\eta}) c_{\vec{r}+\vec{\eta}, \sigma}^\dagger c_{\vec{r}, \sigma} \quad \text{or}
\]  

(1)

\[
= \frac{q_e^2}{\hbar} \sum_{\vec{k}} \frac{d^2 \varepsilon_{\vec{k}}}{dk_x^2} c_{\vec{k}, \sigma}^\dagger c_{\vec{k}, \sigma}
\]  

(2)
\[ \Theta_{xx} = \sum_{p,\sigma} \frac{\partial}{\partial p_x} \left\{ v_p^x (\varepsilon_p - \mu)^2 \right\} c^\dagger_{p,\sigma} c_{p,\sigma} + \frac{U^2}{4} \sum_{\eta,\sigma} t(\bar{\eta}) \eta_x^2 (n_{\bar{r},\bar{\sigma}} + n_{\bar{r}+\bar{\eta},\bar{\sigma}}) c^\dagger_{\bar{r}+\bar{\eta},\sigma} c_{\bar{r},\sigma} \]

\[-\mu U \sum_{\bar{\eta},\sigma} t(\bar{\eta}) \eta_x^2 (n_{\bar{r},\bar{\sigma}} + n_{\bar{r}+\bar{\eta},\bar{\sigma}}) c^\dagger_{\bar{r}+\bar{\eta},\sigma} c_{\bar{r},\sigma} \]

\[-\frac{U}{8} \sum_{\bar{\eta},\bar{\eta}',\sigma} t(\bar{\eta}) t(\bar{\eta}') (\eta_x + \eta_x')^2 \left\{ 3n_{\bar{r},\bar{\sigma}} + n_{\bar{r}+\bar{\eta},\bar{\sigma}} + n_{\bar{r}+\bar{\eta}',\bar{\sigma}} + 3n_{\bar{r}+\bar{\eta}+\bar{\eta}',\bar{\sigma}} \right\} c^\dagger_{\bar{r}+\bar{\eta}+\bar{\eta}',\sigma} c_{\bar{r},\sigma} \]

\[+ \frac{U}{4} \sum_{\bar{\eta},\bar{\eta}',\sigma} t(\bar{\eta}) t(\bar{\eta}') (\eta_x + \eta_x') \eta_x c^\dagger_{\bar{r}+\bar{\eta},\sigma} c_{\bar{r},\sigma} \left\{ c^\dagger_{\bar{r}+\bar{\eta},\bar{\sigma}} c_{\bar{r}+\bar{\eta}+\bar{\eta}',\bar{\sigma}} + c^\dagger_{\bar{r}+\bar{\eta}',\bar{\bar{\sigma}}} c_{\bar{r},\bar{\sigma}} - h.c. \right\} \] . \(1\)

Interesting by product of these formulas: at \( T=0 \), \( <\Phi> \) must vanish being entropy current, and hence the chemical potential can be expressed as a ratio of two operators. This is pretty surprising, and can be verified in some cases: half filled Hubbard model in any dimension for bipartite lattices \( \mu = U/2 \)
Free Electron Limit and Comparison with the Boltzmann Theory

It is easy to evaluate the various operators in the limit of $U \to 0$, and this exercise enables us to get a feel for the meaning of these various somewhat formal objects. We note that

$$
\langle \tau^{xx} \rangle = \frac{2q_e^2}{\mathcal{L}} \sum_p n_\rho \frac{d}{dp_x} \left[ v_{\rho}^x \right] \\
\langle \Theta^{xx} \rangle = \frac{2}{\mathcal{L}} \sum_p n_\rho \frac{d}{dp_x} \left[ v_{\rho}^x (\varepsilon_{\rho} - \mu)^2 \right] \\
\langle \Phi^{xx} \rangle = \frac{2q_e}{\mathcal{L}} \sum_p n_\rho \frac{d}{dp_x} \left[ v_{\rho}^x (\varepsilon_{\rho} - \mu) \right].
$$

At low temperatures, we use the Sommerfield formula after integrating by parts, and thus obtain the leading low $T$ behaviour:

$$
\langle \tau^{xx} \rangle = 2q_e^2 \rho_0(\mu) \langle (v_{\rho}^x)^2 \rangle_\mu \\
\langle \Theta^{xx} \rangle = T^2 \frac{2\pi^2 k_B^2}{3} \rho_0(\mu) \langle (v_{\rho}^x)^2 \rangle_\mu \\
\langle \Phi^{xx} \rangle = T^2 \frac{2q_e \pi^2 k_B^2}{3} \left[ \rho'_0(\mu) \langle (v_{\rho}^x)^2 \rangle_\mu + \rho_0(\mu) \frac{d}{d\mu} \langle (v_{\rho}^x)^2 \rangle_\mu \right],
$$

(1)
We may form the high frequency ratios

\[ S^* = T \frac{\pi^2 k_B^2}{3q_e} \frac{d}{d\mu} \log \left[ \rho_0(\mu) \langle (v_{\mu}^x)^2 \rangle_{\mu} \right] \]

\[ L^* = \frac{\pi^2 k_B^2}{3q_e^2} . \]  

(1)

It is therefore clear that the high frequency result gives the same Lorentz number as well as the thermopower that the Boltzmann theory gives in its simplest form.

The thermal conductivity cannot be found from this approach, but basically the formula is the same as the Drude theory with \( \frac{i}{\omega} \to \tau \).

Some new results for strong correlations and triangular lattice:
Thermopower formula to replace the Heikes-Mott-Zener formula
Leading High temperature term for the Triangular lattice and application to Sodium Cobalt Oxide

\[ S^* = -\frac{\mu}{q_e T} + \frac{q_e \Delta}{T \langle \tau^{xx} \rangle} \]

where

\[ \Delta = -\frac{1}{2} \sum_{\eta, \eta', \vec{r}} (\eta_x + \eta'_x)^2 t(\vec{\eta}) \ t(\vec{\eta}') \ Y_{\sigma', \sigma} (\vec{r} + \vec{\eta}) \ \langle c^\dagger_{\vec{r} + \eta + \eta', \sigma}, c_{\vec{r}, \sigma} \rangle \]

This is a very useful alternate formula to the Heikes-Mott-Zener formula where the second term in Eq above is thrown out. It interpolates very usefully between the standard formulas for low temperature as well as at high temperature. The second term represents the “transport” contribution to the thermopower, whereas the first term is the thermodynamic or entropic part, which dominates at high temperature for \( S^* \) we can actually make a systematic expansion in powers of \( \beta t \), unlike the dc counterpart.
Leading high temp expansion:

$$\langle \tau^{xx} \rangle = 6 \mathcal{L} q_e^2 t \langle \tilde{c}_1^\dagger \tilde{c}_0 \rangle = 3 \mathcal{L} q_e^2 \beta t^2 n (1 - n).$$

$$\{ \tilde{c}_{\tilde{\tau},\sigma}, \tilde{c}_{\tilde{\tau}',\sigma'}^\dagger \} = \delta_{\tilde{\tau},\tilde{\tau}'} \left\{ \delta_{\sigma,\sigma'} (1 - n_{\tilde{\tau},\tilde{\tau}}) + (1 - \delta_{\sigma,\sigma'}) \tilde{c}_{\tilde{\tau},\sigma}^\dagger \tilde{c}_{\tilde{\tau},\tilde{\tau}} \right\}$$

$$\equiv Y_{\sigma,\sigma'} \delta_{\tilde{\tau},\tilde{\tau}'}$$

(1)

$$\Delta \sim -\frac{3}{2} \mathcal{L} t^2 \sum_{\sigma,\sigma'} \langle Y_{\sigma',\sigma} (\tilde{\eta}) \tilde{c}_{\tilde{\eta}+\tilde{\eta}',\sigma}^\dagger \tilde{c}_{\tilde{\eta}',\sigma} \rangle.$$

The spins must be the same to the leading order in $\beta t$ where we generate a hopping term $\tilde{c}_{0,\sigma}^\dagger \tilde{c}_{\tilde{\eta}+\tilde{\eta}',\sigma}$ from an expansion of $\exp(-\beta K)$, and hence a simple estimation yields

$$\Delta = -\frac{3}{4} \mathcal{L} t^2 \beta n (1 - n) (2 - n) + O(\beta^3).$$

This together with $\mu/k_B T = \log(n/2(1 - n)) + O(\beta^2 t^2)$ gives us the result for $0 \leq n \leq 1$

$$S^* = \frac{k_B}{q_e} \left\{ \log[2(1 - n)/n] - \beta t \frac{2 - n}{4} + O(\beta^2 t^2) \right\}.$$
Results from this formalism:

Strong Correlations Produce the Curie-Weiss Phase of NaₙCoO₂

Jan O. Haerter, Michael R. Peterson, and B. Sriram Shastry

Physics Department, University of California, Santa Cruz, California 95064, USA

(Received 21 July 2006; published 28 November 2006)
Magnetic field dep of S(B) vs data
Finite-temperature properties of the triangular lattice $t$-$J$ model and applications to Na$_x$CoO$_2$

Jan O. Hærter, Michael R. Peterson, and B. Sriram Shastry
Conclusions:

• New and rather useful starting point for understanding transport phenomena in correlated matter

• Kubo type formulas are non trivial at finite frequencies, and have much structure

• We have made several successful predictions for NCO already

• Can we design new materials using insights gained from this kind of work?

Useful link for this kind of work:
